

Theme options

- 1) Out of the box: fixed header on scroll on header.php
- 2) **Video** homepage
 - a. replace the entire header.php with the contents of header-video.php (just copy and paste the code into the header.php file, then delete header-video.php)
 - b. In the functions file, uncomment jquery.mb.YTplayer.js
 - c. The video header template is not designed with a fixed header by default, so if you need that, you'll need to play with it. Reference the main header.php – you'll mostly just need to add <header> and </header> tags.
- 3) **Parallax** homepage
 - a. Adjust the settings in header-parallax.php around line 39 so that the data-width and height are equal to the image dimensions.
 - b. Change styles.css parallax-home so that the min-height is equivalent to whatever you want it to be
 - c. Replace the entire header.php file with the contents of header-parallax.php
 - d. In the functions file, uncomment parallax.min.js (around line 42)

Relevant to all options

- Shortcodes changed again - bloginfo('url') became echo home_url(), and bloginfo('template_url') became get_template_directory_uri(). Those codes apparently are just calling the above functions and might become deprecated, so might as well replace them now.
- There is a built-in front-page.php template file, so you'll need to assign this to the homepage. I didn't want header.php to get too confusing.
- The 30em and 48em breakpoints are gone & the theme is using 40em as the main breakpoint. (This is subject to change if it doesn't seem to work as well in practice – let me know!) I did include a 40 to 60em (640px to 960px) for the flexbox footer columns to show at 50% width.
- All the flexbox stuff can be used for as many columns as you want.
- The blog should be a little better than before, so try going to Settings – Reading and setting a page to be your blog.
